Abstract

Motivated by the results of C. Macchiavello and G. M. Palma on entanglement-enhanced information transmission over a quantum channel with correlated noise, we demonstrate how the entanglement teleportation scheme of J. Lee and M. S. Kim gives rise to two uncorrelated generalized depolarizing channels. In an attempt to find a teleportation scheme which yields two correlated generalized depolarizing channels, we discover a novel teleportation scheme, which allows one to learn about the entanglement in an entangled pure input state, but without decreasing the amount of entanglement associated with it.

In quantum mechanics, the formalism of quantum operations, described in detail by Kraus [1], describes the most general possible state change. In this formalism there is an input state ρ_{in} and an output state ρ_{out} , which are connected by a map

$$\rho_{in} \longrightarrow \rho_{out} = \frac{\mathcal{E}(\rho_{in})}{\text{tr}[\mathcal{E}(\rho_{in})]}.$$

The map is determined by a quantum operation $\mathcal{E}$, a linear, trace-decreasing map that preserves complete positivity. The most general form for $\mathcal{E}$ can be shown to be [1]

$$\begin{aligned} \mathcal{E}(\rho_{in}) &= \sum_k A_k \rho_{in} A_k^\dagger, \\ \sum_k A_k^\dagger A_k &\leq I. \end{aligned} \tag{1}$$

The Kraus operators A_k completely specify the quantum operation $\mathcal{E}$. The insight [4, 5] that one can recast the problem of achieving optimal quantum teleportation [2] into one of optimal reversal of quantum operations, enables one to establish a more general connection between quantum operations, or quantum channels, and teleportation schemes. In Ref.[10], it was demonstrated how this connection enables one to explore optimal approximate reversal of quantum operations on a single qubit.

Recently, the problem of classical capacity of quantum channels with time correlated noise was considered by C. Macchiavello and G. M. Palma [9]. In particular, the problem of subjecting quantum states to two correlated or uncorrelated depolarizing channels were analyzed. In the light of the above insight, it is natural to ask what teleportation schemes would give rise to two correlated or uncorrelated generalized depolarizing channels. In this paper, we show how the entanglement teleportation scheme of J. Lee and M. S. Kim [6] yields two uncorrelated generalized depolarizing channels. However, in order to obtain two correlated generalized depolarizing channels, the entangled states shared between the sender and receiver have to be changed. Interestingly, this modification yields an entanglement teleportation scheme, which allows one to learn about the entanglement of a bipartite pure input state, decreasing the fidelity [3] of the teleported state with respect to the input state, but remarkably without changing the amount of entanglement associated with the original input state.

Here, we adopt the following measure of entanglement [6]. Consider a density operator $\tilde{\rho}_{12}$ and its partial transposition $\tilde{\sigma}_{12} = \tilde{\rho}_{12}^{T_1}$ for two 2-level quantum systems. The density

operator $\tilde{\rho}_{12}$ is entangled if and only if $\tilde{\sigma}_{12}$ has any negative eigenvalues. The measure of entanglement $E(\tilde{\rho}_{12})$ defined by

$$E(\tilde{\rho}_{12}) = \max(0, -2 \sum_a \lambda_a^-),$$

where λ_a^- is a negative eigenvalue of $\tilde{\sigma}_{12}$, satisfies the necessary conditions required for every measure of entanglement.

To set the stage, we begin with a description of a general teleportation scheme, which involves a sender, Alice, and a receiver, Bob, sharing a single pair of entangled particles. Alice is in possession of two n -level quantum systems, the input system 1, and another system 2 arbitrarily entangled with a third n -level target system 3 in Bob's possession. Initially the composite system 123 is prepared in a state with density operator $\tilde{\rho}_1 \otimes \chi_{23}$, where $\tilde{\rho}_1$ is an unknown state of the input system 1, and χ_{23} is an arbitrary entangled state of systems 2 and 3. Since the systems 1 and 3 are identical and thus have the same state space, a one-to-one correspondence from the state space of the composite system onto itself can be established by a unitary swap operator $U_{1(2)3}$, which acts on product states according to

$$U_{1(2)3}(|\tilde{a}\rangle_1 \otimes |b\rangle_2 \otimes |c\rangle_3) = |\tilde{c}\rangle_1 \otimes |b\rangle_2 \otimes |a\rangle_3,$$

swapping the states of systems 1 and 3, while leaving system 2 alone. $U_{1(2)3}$ obviously satisfies $(U_{1(2)3})^2 = I_{123}$, the identity operator on the composite system, and $U_{1(2)3}^\dagger = U_{1(2)3}$. When extended to operators Q_{123} on the composite system, the correspondence becomes

$$\tilde{Q}_{123} \leftrightarrow Q_{123} = U_{1(2)3} \tilde{Q}_{123} U_{1(2)3}^\dagger.$$

It follows that

$$\tilde{\rho}_1 \otimes \chi_{23} = U_{1(2)3}(\tilde{\chi}_{12} \otimes \rho_3)U_{1(2)3}^\dagger, \quad (2)$$

where $\tilde{\chi}_{12}$ is the counterpart of χ_{23} .

To teleport the input state $\tilde{\rho}_1$ to Bob's target system 3, Alice performs a generalized measurement on systems 1 and 2. This generalized measurement is described by operators $\tilde{\Pi}_{12}^{ij} \otimes I_3$, where $\tilde{\Pi}_{12}^{ij}$ are Kraus operators on the joint system 12, i labels the outcome of the measurement, and

$$\sum_i \sum_j \tilde{\Pi}_{12}^{ij\dagger} \tilde{\Pi}_{12}^{ij} = I_{12}.$$

If Alice's measurement has outcome i , she communicates her measurement result to Bob via a classical channel. The state of Bob's target system 3 conditioned on Alice's measurement result i is given by

$$\rho_3^i = \frac{1}{p_i} \text{tr}_{12} \left[\sum_j (\tilde{\Pi}_{12}^{ij} \otimes I_3) (\tilde{\rho}_1 \otimes \chi_{23}) (\tilde{\Pi}_{12}^{ij\dagger} \otimes I_3) \right], \quad (3)$$

where

$$p_i = \text{tr}_{123} \left[\sum_j (\tilde{\Pi}_{12}^{ij} \otimes I_3) (\tilde{\rho}_1 \otimes \chi_{23}) (\tilde{\Pi}_{12}^{ij\dagger} \otimes I_3) \right].$$

Substituting Eq.(2) into Eq.(3) gives

$$\rho_3^i = \frac{1}{p_i} \text{tr}_{12} \left[\sum_j (\tilde{\Pi}_{12}^{ij} \otimes I_3) U_{1(2)3} (\tilde{\chi}_{12} \otimes \rho_3) U_{1(2)3}^\dagger (\tilde{\Pi}_{12}^{ij\dagger} \otimes I_3) \right]. \quad (4)$$

Writing

$$\tilde{\chi}_{12} = \sum_k q_k |\tilde{s}_k\rangle_{12} \langle \tilde{s}_k|,$$

where the vectors $|\tilde{s}_k\rangle_{12}$ make up the complete orthonormal set of eigenvectors of $\tilde{\chi}_{12}$ in the joint space of 1 and 2, and performing the partial trace of Eq.(4) in the complete orthonormal basis $|\tilde{P}_l\rangle_{12}$ for the joint system 12 give

$$\begin{aligned} \rho_3^i &= \frac{1}{p_i} \sum_{j,k,l} q_k {}_{12}\langle \tilde{P}_l | (\tilde{\Pi}_{12}^{ij} \otimes I_3) U_{1(2)3} (|\tilde{s}_k\rangle_{12} \langle \tilde{s}_k| \otimes \rho_3) U_{1(2)3}^\dagger (\tilde{\Pi}_{12}^{ij\dagger} \otimes I_3) |\tilde{P}_l\rangle_{12} \\ &= \sum_{j,k,l} \left[\sqrt{\frac{q_k}{p_i}} {}_{12}\langle \tilde{P}_l | (\tilde{\Pi}_{12}^{ij} \otimes I_3) U_{1(2)3} |\tilde{s}_k\rangle_{12} \right] \rho_3 \left[\sqrt{\frac{q_k}{p_i}} {}_{12}\langle \tilde{s}_k | U_{1(2)3}^\dagger (\tilde{\Pi}_{12}^{ij\dagger} \otimes I_3) |\tilde{P}_l\rangle_{12} \right]. \end{aligned}$$

Therefore, ρ_3^i is related to ρ_3 by a quantum operation $\mathcal{E}^i$:

$$\rho_3^i = \mathcal{E}^i(\rho_3) = \sum_m A_3^{im} \rho_3 A_3^{im\dagger}, \quad (5)$$

where

$$\begin{aligned} A_3^{im} &\equiv \sqrt{\frac{q_k}{p_i}} {}_{12}\langle \tilde{P}_l | (\tilde{\Pi}_{12}^{ij} \otimes I_3) U_{1(2)3} |\tilde{s}_k\rangle_{12}, \\ \sum_m A_3^{im\dagger} A_3^{im} &\leq I_3, \end{aligned} \quad (6)$$

and the single index m denotes the triple (j, k, l) .

Next, we consider the entanglement teleportation scheme of J. Lee and M. S. Kim [6], in a slightly more general setting. Alice is in possession of four n -level quantum systems, the two entangled input systems 1 and 2, and another two systems 3 and 5, each arbitrarily

entangled respectively with a fifth and a sixth n -level target systems 4 and 6 in Bob's possession. Initially the composite system 123456 is prepared in a state with density operator $\tilde{\rho}_{12} \otimes \chi_{34} \otimes \chi_{56}$, where $\tilde{\rho}_{12}$ is an unknown entangled state of the input system 12, and χ_{34} and χ_{56} are arbitrary entangled states of systems 34 and 56. To teleport the input state $\tilde{\rho}_{12}$ to Bob's target systems 46, Alice performs generalized measurements on systems 13 and 25. These generalized measurements are described by operators $(\tilde{\Pi}_{13}^{ij} \otimes I_4) \otimes (\tilde{\Pi}_{25}^{i'j'} \otimes I_6)$. If Alice's measurements have outcomes (i, i') , she communicates her measurement results to Bob via classical channels. The state of Bob's target systems 46 conditioned on Alice's measurement results (i, i') is formally given by

$$\begin{aligned}
\rho_{46}^{ii'} &= \frac{1}{p_{ii'}} \text{tr}_{1325} \left[\sum_{j,j'} ((\tilde{\Pi}_{13}^{ij} \otimes I_4) \otimes (\tilde{\Pi}_{25}^{i'j'} \otimes I_6)) (\tilde{\rho}_{12} \otimes \chi_{34} \otimes \chi_{56}) ((\tilde{\Pi}_{13}^{ij} \otimes I_4) \otimes (\tilde{\Pi}_{25}^{i'j'} \otimes I_6))^\dagger \right] \\
&= \frac{1}{p_{ii'}} \text{tr}_{1325} \left[\sum_{j,j'} ((\tilde{\Pi}_{13}^{ij} \otimes \tilde{\Pi}_{25}^{i'j'}) \otimes (I_4 \otimes I_6)) U_{(1)23\hat{4}\hat{5}(6)} (\tilde{\rho}_{12} \otimes \chi_{34} \otimes \chi_{56}) \right. \\
&\quad \left. U_{(1)23\hat{4}\hat{5}(6)}^\dagger ((\tilde{\Pi}_{13}^{ij} \otimes \tilde{\Pi}_{25}^{i'j'}) \otimes (I_4 \otimes I_6))^\dagger \right] \\
&= \frac{1}{p_{ii'}} \text{tr}_{1325} \left[\sum_{j,j'} ((\tilde{\Pi}_{13}^{ij} \otimes \tilde{\Pi}_{25}^{i'j'}) \otimes (I_4 \otimes I_6)) U_{1(2)\hat{3}(4)5\hat{6}} (\tilde{\chi}_{13} \otimes \tilde{\chi}_{25} \otimes \rho_{46}) \right. \\
&\quad \left. U_{1(2)\hat{3}(4)5\hat{6}}^\dagger ((\tilde{\Pi}_{13}^{ij} \otimes \tilde{\Pi}_{25}^{i'j'}) \otimes (I_4 \otimes I_6))^\dagger \right] \tag{7}
\end{aligned}$$

where

$$\begin{aligned}
p_{ii'} &= \text{tr}_{123456} \left[\sum_{j,j'} ((\tilde{\Pi}_{13}^{ij} \otimes \tilde{\Pi}_{25}^{i'j'}) \otimes (I_4 \otimes I_6)) U_{(1)23\hat{4}\hat{5}(6)} (\tilde{\rho}_{12} \otimes \chi_{34} \otimes \chi_{56}) \right. \\
&\quad \left. U_{(1)23\hat{4}\hat{5}(6)}^\dagger ((\tilde{\Pi}_{13}^{ij} \otimes \tilde{\Pi}_{25}^{i'j'}) \otimes (I_4 \otimes I_6))^\dagger \right]
\end{aligned}$$

Here, the unitary swap operator $U_{(1)23\hat{4}\hat{5}(6)}$ acts on product states according to

$$U_{(1)23\hat{4}\hat{5}(6)}(|\tilde{a}\rangle_1 \otimes |\tilde{b}\rangle_2 \otimes |c\rangle_3 \otimes |d\rangle_4 \otimes |e\rangle_5 \otimes |f\rangle_6) = |\tilde{a}\rangle_1 \otimes |\tilde{c}\rangle_2 \otimes |b\rangle_3 \otimes |e\rangle_4 \otimes |d\rangle_5 \otimes |f\rangle_6$$

swapping the states of systems 2 and 3, and those of systems 4 and 5, while leaving systems 1 and 6 alone. It serves to cast the expression for $\rho_{46}^{ii'}$ into a form similar to that of Eq.(3). The other unitary swap operator $U_{1(2)\hat{3}(4)5\hat{6}}$, acts on product states according to

$$U_{1(2)\hat{3}(4)5\hat{6}}(|\tilde{a}\rangle_1 \otimes |\tilde{c}\rangle_2 \otimes |b\rangle_3 \otimes |e\rangle_4 \otimes |d\rangle_5 \otimes |f\rangle_6) = |\tilde{d}\rangle_1 \otimes |\tilde{c}\rangle_2 \otimes |f\rangle_3 \otimes |e\rangle_4 \otimes |a\rangle_5 \otimes |b\rangle_6,$$

swapping the states of systems 1 and 5, and those of systems 3 and 6, while leaving systems 2 and 4 alone. It plays an analogous role to $U_{1(2)3}$ in Eq.(4), establishing a one-to-one

correspondence from the state space of the composite system onto itself, since the systems 12 and 46 are identical and thus have the same state space. Writing

$$\tilde{\chi}_{13} = \sum_k q_k |\tilde{s}_k\rangle_{13} \langle \tilde{s}_k|,$$

$$\tilde{\chi}_{25} = \sum_{k'} q_{k'} |\tilde{s}_{k'}\rangle_{25} \langle \tilde{s}_{k'}|,$$

where the vectors $|\tilde{s}_k\rangle_{13}$ ($|\tilde{s}_{k'}\rangle_{25}$) make up the complete orthonormal set of eigenvectors of $\tilde{\chi}_{13}$ ($\tilde{\chi}_{25}$) in the joint space of 1 (2) and 3 (5), and performing the partial trace of Eq.(7) in the complete orthonormal basis $|\tilde{P}_l\rangle_{13}$ ($|\tilde{P}_{l'}\rangle_{25}$) for the joint system 13 (25) give

$$\begin{aligned} \rho_{46}^{ii'} &= \frac{1}{p_{ii'}} \sum_{j,j',k,k',l,l'} q_k q_{k'} {}_{13}\langle \tilde{P}_l | {}_{25}\langle \tilde{P}_{l'} | ((\tilde{\Pi}_{13}^{ij} \otimes \tilde{\Pi}_{25}^{i'j'}) \otimes (I_4 \otimes I_6)) U_{1(2)\hat{3}(4)5\hat{6}} \\ &\quad (|\tilde{s}_k\rangle_{13} \langle \tilde{s}_k| \otimes |\tilde{s}_{k'}\rangle_{25} \langle \tilde{s}_{k'}| \otimes \rho_{46}) U_{1(2)\hat{3}(4)5\hat{6}}^\dagger ((\tilde{\Pi}_{13}^{ij} \otimes \tilde{\Pi}_{25}^{i'j'}) \otimes (I_4 \otimes I_6))^\dagger |\tilde{P}_l\rangle_{13} |\tilde{P}_{l'}\rangle_{25} \\ &= \sum_{j,j',k,k',l,l'} \left[\sqrt{\frac{q_k q_{k'}}{p_{ii'}}} {}_{13}\langle \tilde{P}_l | {}_{25}\langle \tilde{P}_{l'} | ((\tilde{\Pi}_{13}^{ij} \otimes \tilde{\Pi}_{25}^{i'j'}) \otimes (I_4 \otimes I_6)) U_{1(2)\hat{3}(4)5\hat{6}} |\tilde{s}_k\rangle_{13} |\tilde{s}_{k'}\rangle_{25} \right] \rho_{46} \\ &\quad \left[\sqrt{\frac{q_k q_{k'}}{p_{ii'}}} {}_{13}\langle \tilde{s}_k | {}_{25}\langle \tilde{s}_{k'} | U_{1(2)\hat{3}(4)5\hat{6}}^\dagger ((\tilde{\Pi}_{13}^{ij} \otimes \tilde{\Pi}_{25}^{i'j'}) \otimes (I_4 \otimes I_6))^\dagger |\tilde{P}_l\rangle_{13} |\tilde{P}_{l'}\rangle_{25} \right]. \end{aligned}$$

Therefore, $\rho_{46}^{ii'}$ is related to ρ_{46} by a quantum operation $\mathcal{E}^{ii'}$:

$$\rho_{46}^{ii'} = \mathcal{E}^{ii'}(\rho_{46}) = \sum_m A_{46}^{ii'm} \rho_{46} A_{46}^{ii'm\dagger}, \quad (8)$$

where

$$\begin{aligned} A_{46}^{ii'm} &\equiv \sqrt{\frac{q_k q_{k'}}{p_{ii'}}} {}_{13}\langle \tilde{P}_l | {}_{25}\langle \tilde{P}_{l'} | ((\tilde{\Pi}_{13}^{ij} \otimes \tilde{\Pi}_{25}^{i'j'}) \otimes (I_4 \otimes I_6)) U_{1(2)\hat{3}(4)5\hat{6}} |\tilde{s}_k\rangle_{13} |\tilde{s}_{k'}\rangle_{25}, \\ \sum_m A_{46}^{ii'm\dagger} A_{46}^{ii'm} &\leq I_{46}, \end{aligned} \quad (9)$$

and the single index m denotes the sextuple (j, j', k, k', l, l') .

Now, we are ready to show that, for two-level systems 1, 2, 3, 4, 5 and 6 (from hereon we consider only two-level systems), with

$$\begin{aligned} \chi_{34} &= q_1 |\Phi^+\rangle_{34} \langle \Phi^+| + q_2 |\Phi^-\rangle_{34} \langle \Phi^-| + q_3 |\Psi^+\rangle_{34} \langle \Psi^+| + q_4 |\Psi^-\rangle_{34} \langle \Psi^-|, \\ \chi_{56} &= q_1 |\Phi^+\rangle_{56} \langle \Phi^+| + q_2 |\Phi^-\rangle_{56} \langle \Phi^-| + q_3 |\Psi^+\rangle_{56} \langle \Psi^+| + q_4 |\Psi^-\rangle_{56} \langle \Psi^-| \end{aligned} \quad (10)$$

where $0 \leq q_k \leq 1$, $\sum_{k=1}^4 q_k = 1$,

$$|\Phi^\pm\rangle = \frac{1}{\sqrt{2}}(|00\rangle \pm |11\rangle),$$

$$|\Psi^\pm\rangle = \frac{1}{\sqrt{2}}(|01\rangle \pm |10\rangle),$$

are the Bell states, and

$$\begin{aligned} \tilde{\Pi}_{13}^{1j} = \tilde{\Pi}_{13}^1 = \tilde{\Pi}_{25}^{1j'} = \tilde{\Pi}_{25}^1 = |\tilde{\Phi}^+\rangle\langle\tilde{\Phi}^+|, \quad \tilde{\Pi}_{13}^{2j} = \tilde{\Pi}_{13}^2 = \tilde{\Pi}_{25}^{2j'} = \tilde{\Pi}_{25}^2 = |\tilde{\Phi}^-\rangle\langle\tilde{\Phi}^-|, \\ \tilde{\Pi}_{13}^{3j} = \tilde{\Pi}_{13}^3 = \tilde{\Pi}_{25}^{3j'} = \tilde{\Pi}_{25}^3 = |\tilde{\Psi}^+\rangle\langle\tilde{\Psi}^+|, \quad \tilde{\Pi}_{13}^{4j} = \tilde{\Pi}_{13}^4 = \tilde{\Pi}_{25}^{4j'} = \tilde{\Pi}_{25}^4 = |\tilde{\Psi}^-\rangle\langle\tilde{\Psi}^-|, \end{aligned} \quad (11)$$

then $\mathcal{E}^{11}$ describes two uncorrelated generalized depolarizing channels. Here, we use $|0\rangle$ and $|1\rangle$ to denote an orthonormal set of basis states for each two-level system. Eq.(10) and Eq.(11) allow us to calculate $p_{ii'} = \frac{1}{16}$ for all $1 \leq i, i' \leq 4$. Substituting Eq.(10) into Eq.(7), we obtain

$$\begin{aligned} \tilde{\chi}_{13} &= q_1|\tilde{\Phi}^+\rangle_{13}\langle\tilde{\Phi}^+| + q_2|\tilde{\Phi}^-\rangle_{13}\langle\tilde{\Phi}^-| + q_3|\tilde{\Psi}^+\rangle_{13}\langle\tilde{\Psi}^+| + q_4|\tilde{\Psi}^-\rangle_{13}\langle\tilde{\Psi}^-|, \\ \tilde{\chi}_{25} &= q_1|\tilde{\Phi}^+\rangle_{25}\langle\tilde{\Phi}^+| + q_2|\tilde{\Phi}^-\rangle_{25}\langle\tilde{\Phi}^-| + q_3|\tilde{\Psi}^+\rangle_{25}\langle\tilde{\Psi}^+| + q_4|\tilde{\Psi}^-\rangle_{25}\langle\tilde{\Psi}^-|. \end{aligned}$$

That is, the complete orthonormal set of eigenvectors of $\tilde{\chi}_{13}$ ($\tilde{\chi}_{25}$) in the joint space of 1 (2) and 3 (5) is given by

$$\begin{aligned} |\tilde{s}_1\rangle_{13} &= |\tilde{\Phi}^+\rangle_{13}, \quad |\tilde{s}_2\rangle_{13} = |\tilde{\Phi}^-\rangle_{13}, \quad |\tilde{s}_3\rangle_{13} = |\tilde{\Psi}^+\rangle_{13}, \quad |\tilde{s}_4\rangle_{13} = |\tilde{\Psi}^-\rangle_{13}, \\ |\tilde{s}_1\rangle_{25} &= |\tilde{\Phi}^+\rangle_{25}, \quad |\tilde{s}_2\rangle_{25} = |\tilde{\Phi}^-\rangle_{25}, \quad |\tilde{s}_3\rangle_{25} = |\tilde{\Psi}^+\rangle_{25}, \quad |\tilde{s}_4\rangle_{25} = |\tilde{\Psi}^-\rangle_{25}. \end{aligned} \quad (12)$$

Eq.(9), when $i = i' = 1$, is in this case reduced to

$$A_{46}^{11kk'w'} = \sqrt{\frac{q_k q_{k'}}{p_{11}}} {}_{13}\langle\tilde{P}_l| {}_{25}\langle\tilde{P}_{l'}| ((\tilde{\Pi}_{13}^1 \otimes \tilde{\Pi}_{25}^1) \otimes (I_4 \otimes I_6)) U_{1(2)\hat{3}(4)5\hat{6}} |\tilde{s}_k\rangle_{13} |\tilde{s}_{k'}\rangle_{25}. \quad (13)$$

Making the choice

$$\begin{aligned} |\tilde{P}_1\rangle_{13} &= |\tilde{\Phi}^+\rangle_{13}, \quad |\tilde{P}_2\rangle_{13} = |\tilde{\Phi}^-\rangle_{13}, \quad |\tilde{P}_3\rangle_{13} = |\tilde{\Psi}^+\rangle_{13}, \quad |\tilde{P}_4\rangle_{13} = |\tilde{\Psi}^-\rangle_{13}, \\ |\tilde{P}_1\rangle_{25} &= |\tilde{\Phi}^+\rangle_{25}, \quad |\tilde{P}_2\rangle_{25} = |\tilde{\Phi}^-\rangle_{25}, \quad |\tilde{P}_3\rangle_{25} = |\tilde{\Psi}^+\rangle_{25}, \quad |\tilde{P}_4\rangle_{25} = |\tilde{\Psi}^-\rangle_{25}, \end{aligned} \quad (14)$$

and substituting Eq.(12) and Eq.(14) into Eq.(13) yield two uncorrelated generalized depolarizing channels $\mathcal{E}^{11}$ specified by Kraus operators

$$\begin{aligned} A_{46}^{111111} &= \sqrt{q_1}\sqrt{q_1}I_4 \otimes I_6, \quad A_{46}^{111211} = \sqrt{q_1}\sqrt{q_2}I_4 \otimes \sigma_6^z, \\ A_{46}^{111311} &= \sqrt{q_1}\sqrt{q_3}I_4 \otimes \sigma_6^x, \quad A_{46}^{111411} = \sqrt{q_1}\sqrt{q_4}I_4 \otimes \sigma_6^y, \\ A_{46}^{112111} &= \sqrt{q_2}\sqrt{q_1}\sigma_4^z \otimes I_6, \quad A_{46}^{112211} = \sqrt{q_2}\sqrt{q_2}\sigma_4^z \otimes \sigma_6^z, \end{aligned}$$

$$\begin{aligned}
A_{46}^{112311} &= \sqrt{q_2}\sqrt{q_3}\sigma_4^z \otimes \sigma_6^x, \quad A_{46}^{112411} = \sqrt{q_2}\sqrt{q_4}\sigma_4^z \otimes \sigma_6^y, \\
A_{46}^{113111} &= \sqrt{q_3}\sqrt{q_1}\sigma_4^x \otimes I_6, \quad A_{46}^{113211} = \sqrt{q_3}\sqrt{q_2}\sigma_4^x \otimes \sigma_6^z, \\
A_{46}^{113311} &= \sqrt{q_3}\sqrt{q_3}\sigma_4^x \otimes \sigma_6^x, \quad A_{46}^{113411} = \sqrt{q_3}\sqrt{q_4}\sigma_4^x \otimes \sigma_6^y, \\
A_{46}^{114111} &= \sqrt{q_4}\sqrt{q_1}\sigma_4^y \otimes I_6, \quad A_{46}^{114211} = \sqrt{q_4}\sqrt{q_2}\sigma_4^y \otimes \sigma_6^z, \\
A_{46}^{114311} &= \sqrt{q_4}\sqrt{q_3}\sigma_4^y \otimes \sigma_6^x, \quad A_{46}^{114411} = \sqrt{q_4}\sqrt{q_4}\sigma_4^y \otimes \sigma_6^y,
\end{aligned} \tag{15}$$

where

$$\sigma^x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma^y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma^z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

are the Pauli matrices. It turns out that, with different Alice's measurement outcomes (i, i') we end up with different two uncorrelated generalized depolarizing channels $\mathcal{E}^{ii'}$. These channels differ only in the coefficients $\sqrt{q_k}\sqrt{q_{k'}}$ in front of $I_4 \otimes I_6$, $I_4 \otimes \sigma_6^z$, etc.

For Bob to successfully complete the teleportation protocol, he must perform a (i, i') -dependent trace-preserving quantum operation $\mathcal{R}^{ii'}$:

$$\begin{aligned}
\mathcal{R}^{ii'}(\rho_{46}^{ii'}) &= \sum_n B_{46}^{ii'n} \rho_{46}^{ii'} B_{46}^{ii'n\dagger}, \\
\sum_n B_{46}^{ii'n\dagger} B_{46}^{ii'n} &= I_{46},
\end{aligned} \tag{16}$$

such that the fidelity [3] $F^{ii'}(\rho_{46}, \mathcal{R}^{ii'} \circ \mathcal{E}^{ii'}(\rho_{46}))$ between the input state ρ_{46} and the teleported state $\mathcal{R}^{ii'} \circ \mathcal{E}^{ii'}(\rho_{46})$ is optimal, that is, as close to one as possible. In other words, Bob has to determine $\mathcal{R}^{ii'}$ which optimally reverses $\mathcal{E}^{ii'}$. For simplicity, we assume the input state ρ_{46} is an entangled pure state:

$$\rho_{46} = (\cos\theta|00\rangle + \sin\theta|11\rangle)_{46}(\langle 00| \cos\theta + \langle 11| \sin\theta), \tag{17}$$

with $E(\rho_{46}) = \sin 2\theta$. In Ref.[10], it was shown that the optimal approximate reversal of a generalized depolarizing channel can be achieved using only unitary transformations: $I, \sigma^x, \sigma^y, \sigma^z$. For instance, since $\mathcal{E}^{11}$ describes two uncorrelated generalized depolarizing channels, we have

$$\mathcal{R}^{11}(\rho_{46}^{11}) = B_{46}^{11} \rho_{46}^{11} B_{46}^{11\dagger},$$

where B_{46}^{11} is composed of a tensor product of two unitary operators: $I, \sigma^x, \sigma^y, \sigma^z$. The exact expression for B_{46}^{11} is determined by the relative magnitudes of q_1, q_2, q_3 and q_4 . After some

algebra, we obtain the maximum fidelity

$$\begin{aligned}
F_{\max} &= \sum_{i,i'=1}^4 p_{ii'} F_{\max}^{ii'}(\rho_{46}, \mathcal{R}^{ii'} \circ \mathcal{E}^{ii'}(\rho_{46})) = \sum_{i,i'=1}^4 p_{ii'} \text{tr}_{46}(\rho_{46}, \mathcal{R}^{ii'} \circ \mathcal{E}^{ii'}(\rho_{46})) \\
&= \max((q_1 + q_2)^2 + (q_1^2 - 2q_3q_4 + q_2^2) \sin^2 2\theta, \\
&\quad (q_1 + q_2)^2 + (q_3^2 - 2q_1q_2 + q_4^2) \sin^2 2\theta, \\
&\quad (q_3 + q_4)^2 + (q_3^2 - 2q_1q_2 + q_4^2) \sin^2 2\theta, \\
&\quad (q_3 + q_4)^2 + (q_1^2 - 2q_3q_4 + q_2^2) \sin^2 2\theta, \\
&\quad (q_1 + q_2)(q_3 + q_4) + (q_1 - q_2)(q_3 - q_4) \sin^2 2\theta, \\
&\quad (q_1 + q_2)(q_3 + q_4) - (q_1 - q_2)(q_3 - q_4) \sin^2 2\theta). \tag{18}
\end{aligned}$$

We note that for $q_1 = q_2 = q_3 = \frac{1-\phi}{6}$, and $q_4 = \frac{1+\phi}{2}$, Eq.(18) yields [6]

$$F_{\max} = \frac{1}{9}[(2 + \phi)^2 - (1 - \phi)(1 + 2\phi) \sin^2 2\theta] \tag{19}$$

Also, the amount of entanglement associated with the teleported state is given by

$$E(\mathcal{R}^{ii'} \circ \mathcal{E}^{ii'}(\rho_{46})) = \max(0, \frac{1}{9}[(1 + 2\phi)^2 \sin^2 2\theta] - 2(2 - \phi - \phi^2)). \tag{20}$$

It is impossible to obtain two correlated generalized depolarizing channels from Eq.(7). This is because, by insisting on $\chi_{34} \otimes \chi_{56}$, and demanding that the resulting Kraus operators reduces to Eq.(25), would in general result in requiring Alice's generalized measurements not be of the physically meaningful form in Eq.(7). So, we keep Eq.(11), and instead of Eq.(10), consider

$$\begin{aligned}
\chi_{3456} &= |\chi\rangle_{3456} \langle \chi|, \\
|\chi\rangle_{3456} &\equiv \sqrt{q_1} |\Phi^+\rangle_{34} \otimes |\Phi^+\rangle_{56} + \sqrt{q_2} |\Phi^-\rangle_{34} \otimes |\Phi^-\rangle_{56} + \sqrt{q_3} |\Psi^+\rangle_{34} \otimes |\Psi^+\rangle_{56} + \sqrt{q_4} |\Psi^-\rangle_{34} \otimes |\Psi^-\rangle_{56}, \tag{21}
\end{aligned}$$

where $0 \leq q_k \leq 1$, $\sum_{k=1}^4 q_k = 1$. Replacing $\chi_{34} \otimes \chi_{56}$ in Eq.(7) by χ_{3456} , we obtain

$$\begin{aligned}
\tilde{\chi}_{1325} &= |\tilde{\chi}\rangle_{1325} \langle \tilde{\chi}|, \\
|\tilde{\chi}\rangle_{1325} &\equiv \sqrt{q_1} |\tilde{\Phi}^+\rangle_{13} \otimes |\tilde{\Phi}^+\rangle_{25} + \sqrt{q_2} |\tilde{\Phi}^-\rangle_{13} \otimes |\tilde{\Phi}^-\rangle_{25} + \sqrt{q_3} |\tilde{\Psi}^+\rangle_{13} \otimes |\tilde{\Psi}^+\rangle_{25} + \sqrt{q_4} |\tilde{\Psi}^-\rangle_{13} \otimes |\tilde{\Psi}^-\rangle_{25}. \tag{22}
\end{aligned}$$

Consequently, when $i = i' = 1$, we obtain, instead of Eq.(13),

$$A_{46}^{11kl'l'} = \sqrt{\frac{q_k}{p_{11}}} {}_{13}\langle \tilde{P}_l | {}_{25}\langle \tilde{P}_{l'} | ((\tilde{\Pi}_{13}^1 \otimes \tilde{\Pi}_{25}^1) \otimes (I_4 \otimes I_6)) U_{1(2)\hat{3}(4)5\hat{6}} | \tilde{s}_k \rangle_{13} | \tilde{s}_k \rangle_{25} \quad (23)$$

where

$$|\tilde{s}_1\rangle = |\tilde{\Phi}^+\rangle, |\tilde{s}_2\rangle = |\tilde{\Phi}^-\rangle, |\tilde{s}_3\rangle = |\tilde{\Psi}^+\rangle, |\tilde{s}_4\rangle = |\tilde{\Psi}^-\rangle. \quad (24)$$

Substituting Eq.(14) and Eq.(24) into Eq.(23) gives two correlated generalized depolarizing channels $\mathcal{E}^{11}$ specified by Kraus operators

$$\begin{aligned} A_{46}^{111111} &= \sqrt{\frac{q_1}{\pi_{11}}} I_4 \otimes I_6, \quad A_{46}^{112111} = \sqrt{\frac{q_2}{\pi_{11}}} \sigma_4^z \otimes \sigma_6^z, \\ A_{46}^{113111} &= \sqrt{\frac{q_3}{\pi_{11}}} \sigma_4^x \otimes \sigma_6^x, \quad A_{46}^{114111} = \sqrt{\frac{q_4}{\pi_{11}}} \sigma_4^y \otimes \sigma_6^y. \end{aligned} \quad (25)$$

with probability $p_{11} = \frac{1}{16}\pi_{11}$, where

$$\pi_{11} = 1 + 2(\sqrt{q_1}\sqrt{q_3} + \sqrt{q_2}\sqrt{q_4})c_{11} - 2(\sqrt{q_1}\sqrt{q_4} + \sqrt{q_2}\sqrt{q_3})c_{22} + 2(\sqrt{q_1}\sqrt{q_2} + \sqrt{q_3}\sqrt{q_4})c_{33}. \quad (26)$$

Here, c_{11} , c_{22} and c_{33} are real coefficients in

$$\rho_{46} = \frac{1}{4}(I_4 \otimes I_6 + \vec{a} \cdot \vec{\sigma}_4 \otimes I_6 + \vec{b} \cdot I_4 \otimes \vec{\sigma}_6 + \sum_{r,s=1}^3 c_{rs} \sigma_4^r \otimes \sigma_6^s)$$

with $\sigma^x \equiv \sigma^1$, $\sigma^y \equiv \sigma^2$, and $\sigma^z \equiv \sigma^3$. Therefore, information about the input state could be obtained, in accordance with Ref.[7]. However, we note that it is only information about the associated entanglement encoded via c_{11} , c_{22} , and c_{33} which is obtainable. Information about the individual subsystems 4 and 6, and that about the associated entanglement encoded via c_{rs} , $r \neq s$, is not.

It turns out that, for different $i = i'$, we have different two correlated generalized depolarizing channels $\mathcal{E}^{ii}$ with probability $p_{ii} = p_{11}$. Again, these channels differ only in the coefficients $\sqrt{q_k}$. For $i \neq i'$, we do not have two correlated generalized depolarizing channels specified by Kraus operators of the form in Eq.(25). However, there exists ‘‘partial correlations’’, and the Kraus operators for these channels can be evaluated similarly. The corresponding probabilities are

$$p_{12} = p_{21} = p_{34} = p_{43} = \frac{1}{16}\pi_{12},$$

$$\pi_{12} = 1 - 2(\sqrt{q_1}\sqrt{q_3} + \sqrt{q_2}\sqrt{q_4})c_{11} + 2(\sqrt{q_1}\sqrt{q_4} + \sqrt{q_2}\sqrt{q_3})c_{22} + 2(\sqrt{q_1}\sqrt{q_2} + \sqrt{q_3}\sqrt{q_4})c_{33},$$

$$\begin{aligned}
p_{13} &= p_{24} = p_{31} = p_{42} = \frac{1}{16}\pi_{12}, \\
\pi_{13} &= 1 + 2(\sqrt{q_1}\sqrt{q_3} + \sqrt{q_2}\sqrt{q_4})c_{11} + 2(\sqrt{q_1}\sqrt{q_4} + \sqrt{q_2}\sqrt{q_3})c_{22} - 2(\sqrt{q_1}\sqrt{q_2} + \sqrt{q_3}\sqrt{q_4})c_{33}, \\
p_{14} &= p_{23} = p_{32} = p_{41} = \frac{1}{16}\pi_{12}, \\
\pi_{14} &= 1 - 2(\sqrt{q_1}\sqrt{q_3} + \sqrt{q_2}\sqrt{q_4})c_{11} - 2(\sqrt{q_1}\sqrt{q_4} + \sqrt{q_2}\sqrt{q_3})c_{22} - 2(\sqrt{q_1}\sqrt{q_2} + \sqrt{q_3}\sqrt{q_4})c_{33}. \quad (27)
\end{aligned}$$

Assuming the input state is given by Eq.(17), and employing the above unitary $\mathcal{R}^{ii'}$, we obtain, after some algebra, the maximum fidelity

$$F_{\max} = \max((q_1 + q_2) + (q_3 + q_4) \sin^2 2\theta, (q_3 + q_4) + (q_1 + q_2) \sin^2 2\theta). \quad (28)$$

This is in contrast to Eq.(19) since $F_{\max}$ increases with the amount of entanglement associated with the input state. More interestingly, when we calculate the amount of entanglement associated with the teleported state, we find

$$E(\mathcal{R}^{ii'} \circ \mathcal{E}^{ii'}(\rho_{46})) = \sin 2\theta, \quad (29)$$

equal to the amount of entanglement associated with the input state, Eq.(17).

In conclusion, we have demonstrated how the entanglement teleportation scheme [6] gives rise to two uncorrelated generalized depolarizing channels. In an attempt to find a teleportation scheme which yields two correlated generalized depolarizing channels, we discover a novel teleportation scheme which allows us to learn about the entanglement in the entangled pure input state, but without decreasing the amount of entanglement associated with it.
